 $oldsymbol{eta}$  A Proposed Constrution

(involves an extension of type theory)

Why Are Semi-Simplicial Types Hard?

#### Types in Type Theory

#### Simple type theory:

There is a collection of types; contexts are defined to be lists of types

#### Dependent type theory:

There are collections of length n contexts, along with fundamental projections:

$$\{\star\} = E_0 \stackrel{\partial}{\longleftarrow} E_1 \stackrel{\partial}{\longleftarrow} E_2 \stackrel{\partial}{\longleftarrow} E_3 \stackrel{\partial}{\longleftarrow} \dots$$

#### Type Structures

The previous formulation is fibred, and thus unsuitable for formalisation

We instead work with an indexed equivalent:

```
codata TyStr where
      ty: TyStr \rightarrow Type
      ex : (\mathcal{T} : \mathsf{TvStr}) \to ty \mathcal{T} \to \mathsf{TvStr}
In Agda:
  record TyStr \ell: Type (Isuc \ell) where
     coinductive
     field
       ty: Type \ell
       ex: ty \to \mathsf{TvStr}\,\mathscr{C}
```

#### Contexts

```
codata TyStr where
ty : TyStr \rightarrow Type
ex : (\mathcal{T} : TyStr) \rightarrow ty \mathcal{T} \rightarrow TyStr
```

From this definition, we are able to recover the type of length n contexts:

```
data Ctx (\mathcal{T}: TyStr) (n : \mathbb{N}) where

\emptyset : Ctx zero

\_+\_ : {n : \mathbb{N}}

(\Gamma : Ctx \mathcal{T} n) \rightarrow ty (exs \mathcal{T} \Gamma) \rightarrow Ctx \mathcal{T} (suc n)

exs : (\mathcal{T}: TyStr) {n : \mathbb{N}} \rightarrow Ctx \mathcal{T} n \rightarrow TyStr

exs \mathcal{T} \emptyset = \mathcal{T}

exs \mathcal{T} (\Gamma + A) = ex (exs \mathcal{T} \Gamma) A
```

## Semi-Simplicial Types

Informally, a semi-simplicial type consists of the following infinite list of data:

$$\begin{array}{l} A_0: \mathsf{Type} \\ A_1: A_0 \to A_0 \to \mathsf{Type} \\ A_2: \big\{x\ y\ z: A_0\big\} \to A_1\ x\ y \to A_1\ x\ z \to A_1\ y\ z \to \mathsf{Type} \\ A_3: \big\{x\ y\ z\ w: A_0\big\} \big\{\alpha: A_1\ x\ y\big\} \big\{\beta: A_1\ x\ z\big\} \big\{\gamma: A_1\ x\ w\big\} \big\{\delta: A_1\ y\ z\big\} \\ \big\{\varepsilon: A_1\ y\ w\big\} \big\{\zeta: A_1\ z\ w\big\} \to A_2\ \alpha\ \beta\ \delta \to A_2\ \alpha\ \gamma\ \epsilon \to A_2\ \beta\ \gamma\ \zeta \to A_2\ \delta\ \epsilon\ \zeta \\ \to \mathsf{Type} \\ \dots \end{array}$$

 $A_0$  is a notion of *points*,  $A_1$  is a notion of *lines*,  $A_2$  is a notion of *triangles*,  $A_3$  is a notion of *tetrahedra*, etc. – we are defining all of the *n-simplices* 

#### Problem Statement

Constructing SSTs is one of the most important open problems in HoTT

The problem is usually posed as constructing a function

 $SST : \mathbb{N} \to \mathsf{Type}$ 

such that SST n is the type of n-truncated SSTs

#### Conceptual Refinement 1:

It is better to ask for

SST: TyStr

## Problem Statement [cont.]

We can begin defining SST by copattern matching:

```
SST : TyStr

ty SST =

Type

ty (ex SST A_0) =

A_0 \rightarrow A_0 \rightarrow \text{Type}

ty (ex (ex SST A_0) A_1) =

\{x \ y \ z : A_0\} \rightarrow A_1 \ x \ y \rightarrow A_1 \ x \ z \rightarrow A_1 \ y \ z \rightarrow \text{Type}

ex (ex (ex SST A_0) A_1) A_2 = ?
```

We recover the *n*-truncated SSTs by taking Ctx SST n, and infinite SSTs may be defined as  $Ctx^{\infty}$  SST

Morally, we have passed to an indexed formulation of a problem from a fibred one

#### The Pattern

To discover the pattern, as observed by *Tim Campion*, we make all arguments explicit, and annotate items in the telescopes with binary numbers:

$$\begin{array}{c} A_0: \ \, \mathsf{Type} \\ A_1: \ \, (x:A_0) \ \, (y:A_0) \to \mathsf{Type} \\ \hline 1 \ \, 10 \\ \hline \\ A_2: \ \, (x:A_0) \ \, (y:A_0) \ \, (\alpha:A_1 \ x \ y) \ \, (z:A_0) \ \, (\beta:A_1 \ x \ z) \ \, (\gamma:A_1 \ y \ z) \to \mathsf{Type} \\ \hline 1 \ \, 10 \ \, 11 \ \, 100 \ \, 101 \ \, 110 \\ \hline \\ A_3: \ \, (x:A_0) \ \, (y:A_0) \ \, (\alpha:A_1 \ x \ y) \ \, (z:A_0) \ \, (\beta:A_1 \ x \ z) \ \, (\gamma:A_1 \ y \ z) \\ \hline \\ 1 \ \, 10 \ \, 11 \ \, 1000 \ \, 101 \ \, 110 \\ \hline \\ (f_0:A_2 \ x \ y \ \alpha \ z \ \beta \ \gamma) \ \, (w:A_0) \ \, (\delta:A_1 \ x \ w) \ \, (\epsilon:A_1 \ y \ w) \ \, (f_1:A_2 \ x \ y \ \alpha \ w \ \delta \ \epsilon) \\ \hline \\ 111 \ \, 1000 \ \, 1001 \ \, 1010 \ \, 1010 \\ \hline \\ (\zeta:A_1 \ z \ w) \ \, (f_2:A_2 \ x \ z \ \beta \ w \ \delta \ \zeta) \ \, (f_3:A_2 \ y \ z \ \gamma \ w \ \epsilon \ \zeta) \to \mathsf{Type} \\ \hline \\ 1100 \ \, 1101 \ \, 1110 \ \, 1110 \\ \hline \end{array}$$

### The Pattern [cont.]

The type of each  $A_n$  is a telescope of *items* mapping to Type

- $\blacktriangleright$  Each item has type  $A_m$  ... with zero or more variables applied
- The variable applications are unique and appear in increasing order
- Each item is indexed by a binary number, ranging from 1 to  $1 \dots 10$

Given an item indexed by binary number b, we have to answer two questions:

- (a) Which  $A_m$  appears in its type?
- (b) Which variables are applied to this  $A_m$ ?

## The Pattern [cont.]

We start with some item, indexed by a binary number b:

(a) Which  $A_m$  appears in its type?

The *dimension* of a binary number is one less than the number of 1s that it has e.g. 1101 has dimension 2

A dimension m item uses  $A_m$ 

(b) Which variables are applied to this  $A_m$ ?

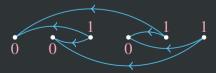

One binary number is a *subset* of another, if, when aligned to the right, the 1s digits of the first lie in a subset of the position of the 1s digits of the second e.g. the non-zero proper subsets of 1101 are 1,100,101,1000,1001,1100 The variables applied to  $A_m$  are indexed by the non-zero proper subsets of b

#### Dependency Lists

For each item, we need to say *yes* or *no* to depending on the previous items We also need to know the dimension of the item

To each n we associated a dimension labelled dependency list These will be linearised directed acyclic graphs with  $\mathbb{N}$ -valued vertex labels

Here is the labelled dependency list of a 2-simplex:

## Properties of the Binary Ordering

In Agda, I have constructed a family of labelled dependency lists corresponding to the pattern seen in the binary ordering of SSTs

Moreover, I have proven the following three properties of this data:

- (a) *Dimension Boundedness*: All items in the labelled dependency list of an *n*-simplex have dimension strictly less than *n*
- (b) *Transitivity*: If an item depends on some other item, then it also depends on all of its dependencies
- (c) The Shape Property: If you take an item of dimension n in some labelled dependency list and prune the items preceding it by discarding all items on which it does not depend, then the resulting labelled dependency list is precisely equal to that of the dependencies of an n-simplex

#### Simple Inverse Categories

In general, given any  $\mathbb N$  indexed family of labelled dependency lists, we can construct untyped syntactic expressions  $A_1$ ,  $A_2$ ,  $A_3$ , etc.

One asks: When will these expressions be well-typed?

The answer is: Exactly when the above three properties hold!

Such data presents a Simple Inverse Category

In the case of semi-simplicial types, we have completely scientifically qualified the nature of the pattern that is apparent when first encountering the problem

However, does this solve the problem of constructing semi-simplicial types?

### The Typing Puzzle

I have formalised untyped syntax, typing derivations, and the construction of untyped expressions from families of labelled dependency lists

AUDIENCE CHALLENGE: Prove, in Cubical Agda, that any simple inverse category results in well-typed syntactic expressions, hence constructing semi-simplicial types "externally"

On GitHub: The result of  $\sim$ 35h of formalisation work setting up this puzzle

The main difficulty was proving things about the binary ordering Conversations with *Emily Riehl* prompted formalising the binary ordering Conversations with *Ophelia Bauckholt* prompted exploring typing *Reed Mullanix* helped me with the formalisation for ~6h

#### Infinite Coherence Issues

Well-typedness derivations are terms of some inductive datatype

If we could construct a function from derivations to Type, we would be done

Issue: HoTT can't eat itself! (as far as we know...)

In the course of constructing such a function, one requires a coherence In the course of proving the coherence, one requires a higher coherence This continues...

A Proposed Construction

## Dependent Semi-Simplicial Types

We think of a semi-simplicial type A as the following infinite list of data:

```
A_0: Type A_1:A_0\to A_0\to \text{Type} A_2:\left\{x\;y\;z:A_0\right\}\to A_1\;x\;y\to A_1\;x\;z\to A_1\;y\;z\to \text{Type} ...
```

#### Conceptual Refinement 2:

We instead seek to construct SST: TyStr such that each A:ty SST is an (infinite) semi-simplicial type

# Dependent Semi-Simplicial Types [cont.]

Suppose that we have that A: ty SST represents a semi-simplicial type

What does B: ty (ex SST A) represent?

We think of a dependent semi-simplicial type B over A as the following infinite list of data:

$$\begin{array}{l} B_0: A_0 \rightarrow \mathsf{Type} \\ B_1: \left\{x\ y: A_0\right\} \rightarrow A_1\ x\ y \rightarrow B_0\ x \rightarrow B_0\ y \rightarrow \mathsf{Type} \\ B_2: \left\{x\ y\ z: A_0\right\} \left\{\alpha: A_1\ x\ y\right\} \left\{\beta: A_1\ x\ z\right\} \left\{\gamma: A_1\ y\ z\right\} \\ \left\{x': B_0\ x\right\} \left\{y': B_0\ y\right\} \left\{z': B_0\ z\right\} \rightarrow A_2\ \alpha\ \beta\ \gamma \\ \rightarrow B_1\ \alpha\ x'\ y' \rightarrow B_1\ \beta\ x'\ z' \rightarrow B_1\ \gamma\ y'\ z' \rightarrow \mathsf{Type} \\ \dots \end{array}$$

## Dependent Semi-Simplicial Types [cont.]

Similarly, we identify C: ty (ex (ex SST A) B) with the data:

$$C_0: \left\{x: A_0\right\} \to B_0 \ x \to \mathsf{Type}$$

$$C_1: \left\{x\ y: A_0\right\} \left\{\alpha: A_1 \ x\ y\right\} \left\{x': B_0 \ x\right\} \left\{y': B_0 \ y\right\}$$

$$\to B_1 \ \alpha \ x' \ y' \to C_0 \ x' \to C_0 \ y' \to \mathsf{Type}$$
...

A dependent n-simplex in B is indexed by a filled in dependent n-simplex in A, as well as a lift of its boundary to B

A doubly dependent n-simplex in C is indexed by a filled in dependent n-simplex in B, as well as a lift of its boundary to C etc.

### SSTs are a Dependent Type Theory

By dependent type theories, I mean B-systems

B-systems have: weakening, elements, shifts (substitution), and zero-variables
This data is subject to nine axioms

On paper, we can show that the TyStr SST described above can be extended to the full structure of a B-system

KEY OBSERVATION: To construct SSTs, you need to work in greater generality!

#### Generalised Induction

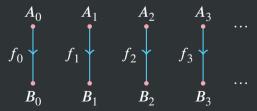

Consider the type of *type streams*:

codata TyStream where

head: TyStream  $\rightarrow$  Type

tail: TyStream  $\rightarrow$  TyStream

Note that type streams have an appropriate notion of morphisms (ladder rungs)

## Generalised Induction [cont.]

What would it mean to inductively define Foo: TyStream?

```
data Foo : TyStream where
```

Z : head Foo

S : Foo  $\rightarrow tail$  Foo

This definition is written in the internal logic of type streams In this case  $S: Foo \rightarrow tail$  Foo is a morphism of type streams

Z: head Foo, and S allows us to promote terms down the stream Morally, Foo should be equivalent to a stream of units

This kind of inductive declaration makes sense

### Defining SSTs

Recall that we have:

```
codata TyStr where
ty : TyStr \rightarrow Type
ex : (\mathcal{T} : TyStr) \rightarrow ty \mathcal{T} \rightarrow TyStr
```

We are now able to give a preliminary definition of semi-simplicial types:

```
codata SST : TyStr where
Z : SST \rightarrow Type
S : (X : SST) \rightarrow Z X \rightarrow ex SST X
```

This is a TyStr-valued coinductive definition in the internal language of TyStr

#### Intuition for the Definition

Given any (possibly dependent) SST A, Z A gives the 0-simplices of A If x: Z A is a 0-simplex, S A x is the *slice* of A over x

The simplices of the slice are mapping objects

$$ZA$$
  $Z(SAx)$   $Z(S(SAx)(y, \alpha))$ 

$$x$$

$$\alpha$$

$$\alpha$$

$$y$$

$$y$$

The number of new data in successive slices goes up by a factor of two

### The Z Projection

We have that  $Z: SST \rightarrow Type$ 

This should be a morphism of TyStrs, so we need to interpret Type as a TyStr

We construct the universe as follows:

```
\mathscr{U}' : Type \rightarrow TyStr

ty (\mathscr{U}' A) = A \rightarrow Type

ex (\mathscr{U}' A) B = \mathscr{U}' (\Sigma A B)

\mathscr{U} : TyStr

ty \mathscr{U} = Type

ex \mathscr{U} A = \mathscr{U}' A
```

### Dependent Type Structures

A morphism  $\mathcal{T} \to \mathcal{U}$  is equivalent to a dependent type structure over  $\mathcal{T}$ 

We can define this data as follows:

```
codata TyStr<sup>d</sup> (\mathcal{T}: TyStr) where
ty^{d} : TyStr^{d} \mathcal{T} \rightarrow ty \mathcal{T} \rightarrow Type
ex^{d} : (\mathcal{S} : TyStr^{d} \mathcal{T}) (A : ty \mathcal{T}) \rightarrow ty^{d} \mathcal{S} A
\rightarrow TyStr^{d} (ex \mathcal{T} A)
```

We will work under the assumption that Z: TyStr<sup>d</sup> SST

### The S Projection

We have that  $S:(X:SST) \rightarrow ZX \rightarrow exSSTX$ 

This should be a morphism of dependent type structures over SST

We thus need to define  $EX \mathcal{T}$ : TyStr<sup>d</sup>  $\mathcal{T}$ 

In general, suppose that we have  $\Gamma = A \leftarrow B \leftarrow C \leftarrow D$ :  $Ctx \mathcal{T}4$ 

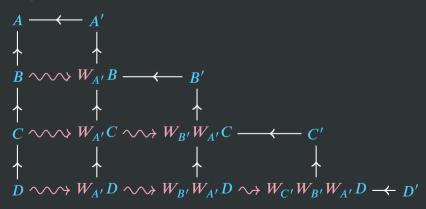

To define S: TyStr<sup>d</sup>  $\mathcal{T}$ , we have to specify the  $\Gamma$ -indexed dependent contexts

Thus we must give meaning to  $\Gamma' = A' \Leftarrow B' \Leftarrow C' \Leftarrow D' : Ctx^d \& \Gamma$ 

### The *EX* Diagram

In order to define  $EX \mathcal{T}$ , we need  $\mathcal{T}$ : TyStr to be equipped with weakening

The meaning of  $\Gamma' = A' \Leftarrow B' \Leftarrow C' \Leftarrow D' : Ctx^d (EX \mathcal{T}) \Gamma$  is:

#### Simplex Extraction

Suppose that we have  $\mathcal{T}$ : TyStr, equipped with a  $\mathcal{W}$ : WkStr  $\mathcal{T}$ 

A ZS-structure on  $(\mathcal{T}, \mathcal{W})$  consists of Z: TyStr<sup>d</sup>  $\mathcal{T}$ , and S, a morphism of TyStr<sup>d</sup>s over  $\mathcal{T}$  from Z to EX  $\mathcal{T}$ 

*S* induces, in particular, maps  $Ctx^d Z \Gamma \to Ctx^d (EX \mathcal{T}) \Gamma$ 

With this data, every A:  $ty \mathcal{T}$  becomes an (infinite) SST

Similarly, every  $B: ty (ex \mathcal{T}A)$  becomes a dependent SST

How do we extract  $A_0$ ,  $A_1$ ,  $A_2$ , etc. from A?

# Simplex Extraction [cont.]

We start with  $A: ty \mathcal{T}$ , this gives us  $\Gamma_0 = \emptyset + A: Ctx \mathcal{T} 1$ 

The type  $A_0$  of 0-simplices is given as  $ty^d Z A$ : Type

If we choose  $x:\mathit{ty}^{\mathsf{d}}$  Z A, then we obtain a Z-section  $\varnothing + x:\mathit{Ctx}^{\mathsf{d}}$  Z  $\Gamma_0$ 

Applying S to this Z-section turns it into  $\varnothing + Sx : Ctx^d$  ( $EX \mathscr{T}$ )  $\Gamma_0$ 

By the *EX*-diagram, this *EX*-section defines  $\Gamma_1 = \emptyset + A + Sx : Ctx \mathcal{T}2$ 

Next we form a Z-section of this context:  $\varnothing + y + \alpha$ :  $Ctx^d Z \Gamma_1$ 

Note that  $y: ty^d Z A$ , so it's a 0-simplex as well

 $\alpha$ :  $ty^d$  (ex<sup>d</sup> Z A y) (S x) has the type of 1-simplices with boundary x and y

# Simplex Extraction [cont.]

Next, we apply S to  $\varnothing + y + \alpha$  to get  $\varnothing + S$  y + S  $\alpha$ :  $Ctx^d$   $(EX \mathscr{T})$   $\Gamma_1$  By the EX-diagram, we get  $\Gamma_2 = \varnothing + A + S$   $y + W_S$   $_y$  (S x) + S  $\alpha$ : Ctx  $\mathscr{T}$  4 We Z-section again via  $\varnothing + z + \beta + \gamma + f_0$ :  $Ctx^d$  Z  $\Gamma_2$  We have that z:  $ty^d$  Z A and  $\beta$ :  $ty^d$   $(ex^d$  Z A z) (S y)

We have that:

$$f_0: ty^d \left(ex^d \left(ex^d \left(ex^d ZAz\right) (Sy)\beta\right) \left(W_{Sy}(Sx)\right)\gamma\right) (S\alpha)$$

Then  $f_0$  has the type of 2-simplicies with boundary x, y, z,  $\alpha$ ,  $\beta$ ,  $\gamma$ 

So z is a 0-simplex, and  $\beta$  is a 1-simplex joining y to z

## Simplex Extraction [cont.]

We previously sectioned  $\Gamma_2 = \emptyset + A + S y + W_{S y} (S x) + S \alpha$ 

Then, in  $\varnothing + z + \beta + \gamma + f_0 : Ctx^d Z \Gamma_2$ , we have:

$$\gamma$$
:  $ty^d$   $\left(ex^d \left(ex^d Z A z\right) (S y) \beta\right) \left(W_{S y} (S x)\right)$ 

This ought to be a 1-simplex joining x to z, i.e. of type  $ty^d$   $(ex^d Z A z)$  (S x)

The type that we see falsely suggests that  $\gamma$  depends on y and  $\beta$ 

Morally, the weakening should cancel the extension

This would follow if Z preserved weakening

In the category of TyStrs with weakening, morphisms should preserve weakening

#### Status Report

In present-day Agda, the universal property constructs unreduced simplex types

With rewriting, we can see that if Z and S preserve weakening definitionally, then we extract the correct reduced simplex types

We are working on a type theory which lets us work with TyStrs with weakening

Further, in any example of universal property data in which preservation is definitional, we can construct the corresponding SSTs in present-day Agda

In particular, we are able to construct the singular semi-simplicial types

#### Singular SSTs

Given a type X, we think of X as a space

A space has points, lines, triangles, etc.

The corresponding SST is called Sing X

How do we use our universal property to construct this?

## Singular SSTs [cont.]

We are going to construct singular SSTs from some type structure  $\mathcal{T}$  It turns out that we have to suitably generalise by taking  $\mathcal{T} = \mathcal{U}$  This has a standard weakening structure (we're weakening types)

Z is defined to be the tautological dependent type structure on  $\mathscr U$ 

Suppose that  $\Gamma = \emptyset + A + B + C : Ct \times \mathcal{U} 3$ 

Then  $\emptyset + x + y + z : Ctx^d Z \Gamma$  consists of x : A, y : B x, and z : C(x, y)

S is defined such that for x:A, we have  $S x = \lambda y$ .  $x \equiv y$ 

For the higher cases, we use cleverness involving cubical dependent path types

# Singular SSTs [cont.]

```
Z': \{X: \mathsf{Type}\ \ell\} \to X \to \mathsf{ZStr}\ (\mathcal{U}'\ X)\ \ell
tv^{z} (Z' x) A = A x
ex^{z}(Z'x) a = Z'(x, a)
Z: \mathsf{ZStr} (\mathscr{U} \ell) \ell
tv^{z} Z A = A
ex^{z} 7 a = 7' a
S': \{X \mid Y : \text{Type } \ell\} \{f : X \rightarrow Y\} \{y : Y\} \{p : \{x : X\}\} \{y \in Y\} \{x : X\}
  SStr (replace f) (Z'v) (W-W'X)
fun^s (S' f \lor p) {A} a_0 = \lambda \{(x , a_1) \rightarrow PathP (\lambda i \rightarrow A (p \times i)) a_0 a_1\}
up^{s} (S' f v p) \{A\} a =
  S' (\lambda x \rightarrow f \text{ (fst (fst x))}, \text{ snd (fst x))} (y, a)
       (\lambda \times i \rightarrow p \text{ (fst (fst x)) } i, \text{ snd } x i)
S: SStr (idTvMor (\mathcal{U} \ell)) Z \mathcal{W}-\mathcal{U}
fun^{s} S a_{0} a_{1} = a_{0} \equiv a_{1}
uv^{s} S a = S' \text{ fst } a \text{ snd}
```

# Singular SSTs [cont.]

Applying the simplex extraction algorithm in Agda yields the following output:

```
x:X
                                                                   w:X
v:X
                                                                   \delta: z \equiv w
\alpha: x \equiv v
                                                                   \epsilon: v \equiv w
z:X
                                                                   f_1: PathP (\lambda i \rightarrow v \equiv \delta i) \beta \epsilon
\beta: v \equiv z
                                                                   \zeta: x \equiv w
                                                                   f_2: PathP (\lambda i \rightarrow y \equiv \delta i) \gamma \zeta
\gamma: x \equiv z
f_0: PathP (\lambda i \rightarrow x \equiv \beta i) \alpha \gamma f_3: PathP (\lambda i \rightarrow y \equiv \epsilon i) \alpha \zeta
   \Delta_0: PathP (\lambda i \rightarrow \text{PathP} (\lambda j \rightarrow x \equiv f_1 i j) \alpha (f_2 i)) f_0 f_3
```

#### Summary

We can codify the pattern in SSTs via a simple inverse category

Audience Puzzle: show that this leads to externally well-typed expressions

However, it seems that these cannot be internalised

When working with TyStrs with weakening, SST acquires a universal property
We can express this in terms of non-Type-valued coinduction
This universal property lets us construct singular semi-simplicial types
The type theory that lets us do this in generality is under construction

A research writeup and associated code may be found at:

Thank you for listening to my talk!
